Systemic Manifestations of Ehlers-Danlos Syndrome Hypermobility Type

Abstract
Ehlers-Danlos syndrome Hypermobility type is a hereditary connective tissue disease characterized by generalized joint Hypermobility, joint instability, skin changes and musculoskeletal pain. Signs and symptoms of Ehlers-Danlos syndrome Hypermobility type are classified as musculoskeletal or extra skeletal. Pain and fatigue are the most common complaints in the clinical practice. Due to impaired postural structure and biomechanics, associated conditions include nocturnal insomnia and early morning drowsiness, dysautonomia, dyslexia and neuropsychological disorders and illnesses related to impaired restorative phases of sleep. The patient has musculoskeletal pain that affects the activities of daily life and work, as well as shifting the biological clock. It is therefore important to understand the order of appearance and prevalence of signs and symptoms in the general population suggesting a need to investigate the order of these symptoms in population studies.

Keywords: Hypermobility; Ehlers-danlos hypermobility type; Neuropsychological disorders; Comorbidities; Anxiety; Dyslexia; Fatigue; Pain; Collagen

Abbreviations: EDS: Ehlers-Danlos Syndrome; EDS-HT: Ehlers-Danlos Syndrome Hypermobility Type; JH: Joint Hypermobility; GH: Generalized Joint Hypermobility; GI: Gastrointestinal

Introduction
Joint Hypermobility (JH) can be the extreme of the range of motion or a condition in a group of hereditary connective tissue disorders. It is influenced by age, gender and ethnicity, has a Gaussian distribution in the physiological range of motion and is considered to be a genetically determined deviation from normality [1,2]. The JH can be identified in up to 64.6% of the population, including children [3-7]. Recently a population study was published that identified JH in 41% of Brazilian children [7]. Characterization of this disorder is achieved using the Beighton score [8]. Ehlers-Danlos syndrome (EDS) is a hereditary connective tissue disease caused by genetic alterations related to collagen that produce other health conditions. This syndrome is characterized by generalized JH, joint instability and pain. It has multisystem manifestations and clinical variability affecting the skin, ligaments, joints, blood vessels and internal organs [9]. According to Hamonet et al. [10], a high frequency of EDS is used in the clinical practice, but the differences of evaluation systems does not allow reliable calculations of its prevalence to be made [2]. EDS is classified by the Villefranche criteria into six subtypes with Ehlers-Danlos Syndrome Hypermobility type (EDS-HT) having the highest prevalence. The phenotypic expression of EDS-HT is variable, even within the same family, making diagnosis a challenge [9] and resulting in under diagnosis of the syndrome [5]. As the terms Joint Hypermobility Syndrome (JHS) and EDS-HT are often used differently in the same classification, the etiology must be confirmed at the molecular level [11]. The signs and symptoms of EDS-HT are classified as musculoskeletal or extra skeletal [5]. Henkel [12] cites a study by Grahamie [1] on the main categories of clinical presentation. These include sagging of musculoskeletal tissue, pain in the joints and in the non-inflamed spine, dislocations, soft tissue injuries and problems with support structures, such as the pelvic floor. Moreover the subject suffers amplification of pain, which can lead to muscle intolerance and deconditioning, and finally, psychosocial sequels, anxiety, depression, obesity, isolation and anger. All these conditions are often targeted by medical professionals who are unable to help the patient.

The EDS-HT may have systemic manifestations from the mouth to the anus, some of which are benign, and others may be lethal. A thorough knowledge of gastrointestinal (GI) manifestations and their management is mandatory to avoid unnecessary morbidity and mortality [13-15]. An increased rate of celiac disease was identified in EDS-HT, suggestive of intestinal malabsorption, a possible factor for fatigue [16,17]. Moreover, individuals have psychiatric disorders and psychosocial impairment [18], and a high prevalence of anxiety disorders from simple phobias to panic disorders [19]. The EDS-HT is characterized by pain, fatigue, proprioceptive dysfunctions, hemorrhagic syndromes, dysautonomia, dystonia and digestive tract, vesicophretrical, respiratory, dental, otorhinolaryngological, ophthalmological, gynecological, obstetrical and cognitive disorders, among others. The pains are diffuse and are among the most disabling symptoms in patients with fatigue and proprioceptive disorders; at times, even from early childhood, the whole body is described as painful [20]. Fatigue and musculoskeletal pain generally receive little medical attention [21]. Chronic fatigue is present in most patients, manifesting with a persistent sensation of fatigue, lack of energy and feeling of exhaustion, with impairment to concentration [16]. Pain is the main complaint, with chronicity and consequencens on quality of life, including sleep loss, and impaired social and work relationships, sexual function, and physical and recreational activities resulting in depression with psychosocial consequencens [22](Figure 1-14).

Figure 11. Passive apposition of the thumb to the flexor region of the forearm.

Figure 12. Hyperextension of the elbow joint beyond 10°.
Method

The search strategy of this study was an up-to-date review of the specialized literature on JH, EDS-HT, including the signs, symptoms, diagnoses and comorbidities related to EDS and the different techniques of updating references used by a simple search and their effectiveness. Articles in English, French and Spanish published in the BIREME, SciELO Brazil, LILACS and PUBMED electronic databases from 1973 to 2017 were investigated using the keywords Hypermobility, Ehlers-Danlos, Ehlers-Danlos syndrome Hypermobility type, gastrointestinal motility, sleep disorders, pain, fatigue, dysautonomia, dyslexia and anxiety. Duplicate publications were excluded.

Discussion and Conclusion

The EDS-HT is very common and has systemic manifestations. Pain and fatigue are the most common complaints in the daily clinical practice, followed by nocturnal insomnia and morning drowsiness, dysautonomia, dyslexia and neuropsychological disorders. Furthermore, subjects suffer from conditions related to the restorative phases of sleep such as musculoskeletal pain, impaired concentration and cognitive deficits, which are explained, at least in part, by higher organic energy consumption [10,17,18,20,22]. In this context, there is impairment to activities of daily living, and to the professional and sports life of individuals, a situation that requires an understanding of the order of appearance and prevalence of signs and symptoms in the general population with an emphasis on this diversity of manifestations, a condition that currently suggests analyzes of signs and symptoms based on disturbances of the hyper mobile spectrum.
